

LightBall Controller – Documentation

This pack includes a simple controller script used to manage the color and emission of the decorative light balls.

It is intended to be placed on a **parent object**, automatically updating all child light balls to keep their material and emission colors perfectly synced with the selected light color.

How It Works

The script performs two main functions:

1. Updates the Light Component color

- You can select any color directly in the Inspector.
- Intensity and range can also be adjusted freely.

2. Automatically updates the material color

- Both the Albedo and Emission colors of the material are set to match the selected light color.
- This prevents the issue where the light balls stay white while casting colored light.

How to Use

1. Create an empty GameObject (or use your existing parent object).
2. Attach the **LightBallController** script to the **parent**.
3. Place all light-ball objects as **children** of this parent.
4. In the Inspector, configure:
 - **Light Color** – the desired color for all bulbs.
 - **Intensity** – brightness of the emission.
 - **Blinking Settings** – optional blinking behaviour.

Requirements

- Each child light ball must have:
 - A material with **Emission** enabled.
 - A renderer component (MeshRenderer).

Notes

- You can duplicate or rearrange the child lights freely; the parent script will always find and update them.
- Ideal for Christmas lights, decoration strings, stylized props, or fantasy assets.
- Fully compatible with URP.
